## Executive Summary

This report has been prepared to satisfy the listing requirements of Section 303(d) and the reporting requirements of Section 305(b) and 314 of the Clean Water Act. The report is the principal means by which the American Samoa Environmental Protection Agency (AS-EPA), Congress, and the public evaluate whether territorial waters meet water quality standards, the progress made in maintaining and restoring water quality, and the extent of remaining problems. The report was prepared in accordance with *Guidance for 2006 Assessment, Listing and Reporting Requirements Pursuant to Sections 303(d), 305(b) and 314 of the Clean Water Act* (USEPA 2005) and 2006 Integrated Report Guidance (IRG), supplemented by EPA's 2008, 2010, 2012, 2014, and 2016 memorandums.

The Territory of American Samoa lies roughly 14 degrees south of the equator between longitudes 169 and 173 west and about 2,500 miles southwest of Hawaii. The principal islands are Tutuila (with 97% of the population), Aunu'u, and the Manu'a. The islands of American Samoa are volcanic in origin and exhibit the rugged topographic relief common to the Pacific volcanic islands. The climate of the territory is tropical, with uniform high temperatures and high humidity throughout the year. The population of the territory was 55,519 in 2010. Factors such as population, inadequate land-use permitting, and increased production of solid waste and sewage have detrimentally impacted water quality in streams and coastal waters of the Territory.

For this report AS-EPA assembled and evaluated all existing and readily available data and information relating to the categories of waters specified in 40 CFR§130.7(b)(5) for sampling and analyses completed between October 2013 and September 2015 (FY14 and FY15). The narrative section of the report, as well as assessments presented in Appendix B and Appendix C, reflect the data collected in FY14 and FY15. AS-EPA also completed a cumulative assessment of data from FY03 to FY15. The cumulative assessment is presented in Appendix A.

The primary unit of assessment used by AS-EPA for this report is the watershed. The total surface area of American Samoa is very small, only 76.1 sq. miles, which is divided into 41 watersheds with an average size of 1.8 sq. miles. Water quality monitoring, along with coral / fish / benthic monitoring, covers 31 of the 41 watersheds, and also covers >95% of the population of American Samoa. Waterbodies in the watersheds were assessed according to levels of use support.

In FY14 and FY 15 104.9 out of a total of 257.5 stream miles were assessed. For the goal to Protect and Enhance Public Health, 104.9 stream miles were assessed for Swimming and all found to be Not Supporting (poor) (Table C2). For the goal Protect and Enhance Ecosystems (Aquatic Life) 90.5 miles were assessed. Of this total, 83.0 miles were Fully Supporting (good), 7.5 miles were Not Supporting (fair), and 0 miles were Not Supporting (poor) (Table C2). The Major Cause/Stressor identified for this reporting period was Pathogen Indicators. The major assessed sources of impairment were Collection System Failure and Intensive Animal Feeding Operations.

In FY14 and FY 15 111.2 out of a total of 149.5 ocean shoreline miles were assessed. For the goal to Protect and Enhance Public Health, 103.3 shoreline miles were assessed for swimming. Of this total, 51.3 miles were Fully Supporting (good), 3.3 miles were Not Supporting (fair), and 48.7 miles were Not Supporting (poor). For the goal to Protect and Enhance Public Health, 7.9 shoreline miles were assessed for fish consumption, and 7.9 miles were found to be Not Supporting (poor) (Table C5). The Major Causes/Stresses identified for this reporting period were PCBs, Metals (Mercury) and Pathogen Indicators. (Table C6). The major sources of impairment were Collection System Failure and Intensive Animal Feeding Operations.

No wetlands assessments were conducted during this reporting period.

A repeat probabilistic based survey was conducted for the reef flats of Tutuila and Aunuu islands in 2015. Results will be available in the 2018 Integrated Report.

Aquifer monitoring data for all 11 hydrogeologic settings (individual public water systems) were assessed. No parameters were detected at concentrations exceeding the MCLs and all Nitrate concentrations were  $\leq 5$  mg/l. A Ground Water Under the Direct Influence of Surface Water (GUDI) study has been completed on 40 wells, and no new GUDI wells have been detected in the system other than the 9 wells that have already been determined GUDI. This is the cause of the current Boil Water Notice in areas of the ASPA water system. ASPA has shutdown 1 of the 9 GUDI Wells and is working diligently to drill replacement wells so the Boil Water Notice can be lifted.

The 2016 303(d) list reflects all data collected between FY03 and FY15. Twenty three watersheds are listed for impaired streams for pollutants including enterococcus, nutrients, turbidity, and DO. One watershed was added to the list in 2016 for impaired streams. Twenty four watersheds are listed for impaired ocean shorelines for the pollutants enterococcus and undetermined NPS stressors. No watersheds were added to the 2016 list for impaired ocean shorelines. No waterbodies were removed from the previous (2014) list.

A TMDL for the pollutant enterococcus in beaches and streams was completed in 2013 and approved in 2015. The new high priority pollutants for TMDL development (2018) are Total Nitrogen (TN) and Total Phosphorus (TP) in streams.

## I Overview

The American Samoa Environmental Protection Agency (AS-EPA) has a responsibility to monitor, assess, and protect water quality for the Territory of American Samoa. U.S. federal and American Samoa local environmental legislation and regulations all apply in American Samoa.

This report has been prepared to satisfy the listing requirements of Section 303(d) and the reporting requirements of Section 305(b) and 314 of the Clean Water Act. The report is the principal means by which AS-EPA, Congress, and the public evaluate whether territorial waters meet water quality standards, the progress made in maintaining and restoring water quality, and the extent of remaining problems. The report was prepared in accordance with *Guidance for 2006 Assessment, Listing and Reporting Requirements Pursuant to Sections 303(d), 305(b) and 314 of the Clean Water Act* (USEPA 2005) and 2006 Integrated Report Guidance (IRG), supplemented by EPA's 2008, 2010, 2012, 2014, and 2016 memorandums.

The narrative section of the 2016 report, as well as assessments presented in Appendix B and Appendix C, reflect data collected between October 2013 and September 2015 (FY14 and FY15) only. A cumulative assessment that reflects all data collected between FY03 and FY15 is presented in Appendix A.

### i. Geographical Summary

The Territory of American Samoa lies roughly 14 degrees south of the equator between longitudes 169 and 173 west and about 2,500 miles southwest of Hawaii. The principal islands are Tutuila, Aunu'u, and the Manu'a islands (a cluster of three islands, Ta'u, Ofu and Olosega, located about 65 miles east of Tutuila). Swains Island, a small island with a population of less than 25 and Rose Atoll, an uninhabited atoll about 120 miles east of Tutuila, make up the remainder of the territory. The population of the territory is 55,519 (2010 census), of which approximately 97% live on the island of Tutuila.

The islands of American Samoa are volcanic in origin and exhibit the rugged topographic relief common to the Pacific volcanic islands. The climate of the territory is tropical, with uniform high temperatures and high humidity throughout the year. Mean daily temperature during the year varies from about 78 to 82 degrees Fahrenheit. The maximum altitude is about 3,180 ft. above mean sea level at the summit of Lata Mountain on Ta'u Island. Tutuila, with an area of 53 square miles, is the largest island in the territory. It is approximately 20 miles long and ranges in width from less than one mile, to a maximum of 5 miles at the Tafuna-Leone plain. A sharp-crested ridge 1,000 to 2,000 feet high with steeply eroded slopes dominates the entire length of the island.

The steep, variable topography of Tutuila effects localized rainfall amounts. The airport at Tafuna receives about 125 in. (3,180 mm) but Pago Pago receives nearly 200 in (4,090 mm). The crest of the range at Mt. Alava, altitude 1,600 ft. (914 m), receives considerably more than 250 in (6,350 mm). The driest months are June through September and the wettest are December through March, but heavy showers can occur in any month.

## **ii. Territorial Water Quality Review**

### **Fresh Surface Waters**

The small, steep watersheds and periodic intense rainfall cause highly variable flows in the nearly 260 miles of American Samoa's perennial streams. Despite these highly variable flows, the streams of American Samoa support a variety of aquatic species, several of which may be harvested for consumption. Designated uses include potable water supplies, support of indigenous wildlife, and aesthetic and recreational enjoyment. Stream water quality is most affected by development along a stream that changes the hydrology and shade along a stream, by development within a watershed that causes erosion and increased turbidity, and by nutrient and bacterial pollution from poorly constructed human and pig waste disposal systems. In some areas, improved service by sewage lines and subsequent decrease in the number of poorly constructed septic systems, as well as improved pig waste management, has improved stream water quality.

### **Ground Waters**

The Tafuna-Leone plain is the site of the majority of American Samoa's residential and business development. The plain is also the site of the majority of the wells that pump ground water for distribution. Because volcanic stratum of Tutuila is highly permeable and does not have a great capacity to filter, there is a constant risk of groundwater contamination as pollution migrates from the surface with rainwater. The greatest threats to groundwater quality in American Samoa are pesticide residues, pollutants associated with automobiles, and pathogen and nutrient pollution from poorly constructed human and pig waste disposal systems.

Ground Water Under the Direct Influence of Surface Water (GUDI) studies have been initiated to determine if existing wells are under the direct influence of surface water. As of FY15, GUDI studies have been completed on 40 wells, and 9 wells have been determined GUDI. The water system operator is working diligently to drill replacement wells.

As in many small tropical islands with highly permeable soils, the fresh water aquifer floats on a layer of salt water beneath the ground. Rare dry periods of two- to three-months duration can result in critical drinking water shortages as salt water intrudes on the depleted fresh water lens.

### **Wetlands**

American Samoa possesses a number of small but very important wetland habitats. The wetlands include coastal mangrove swamps, inland freshwater marshes and some cultivated *taro* fields. Designated uses include support of indigenous aquatic and terrestrial life, fishing, food cultivation and gathering, recreation, flood control and groundwater recharge. Wetlands in the territory are being lost or degraded by urban growth and development as a result of population increase.

## Ocean Shoreline

American Samoa has nearly 150 miles of coastline. Fringing coral reefs that surround all of the islands in the territory characterize the embayments and open coastal waters of American Samoa. Designated uses include fishing and food gathering, recreation, support of marine life, mariculture, and scientific investigations. The reefs also provide a buffer for the islands against the impact of waves. The greatest threats to near-shore water quality and to the health of the reefs in American Samoa are from runoff from the land, especially pathogen and nutrient pollution from poorly constructed human and pig waste disposal systems as well as increased turbidity and nutrients from erosion. Solid waste, i.e. improperly disposed of trash, is another source of pollution in open coastal waters and embayments.

Pago Pago harbor is the most industrialized embayment in the Territory, with over a century of development subsequent to the creation of the Territory under the United States. As well as the sources of water quality impairments mentioned above for embayments in general, Pago Pago Harbor is affected by pollution from marina and port traffic, a small shipyard, and in the outer harbor effluent from the tuna canneries and sewage treatment plant. All point sources have National Pollutant Discharge Elimination System (NPDES) permits. Due to the segregation and transportation of cannery waste beyond the inner harbor, better treatment of sewage, and more effective monitoring and prosecution by the Coast Guard of commercial vessels that pollute the harbor, the water quality in the inner harbor has greatly improved in the last three decades.

There are several special management areas within the Territory's open coastal waters including Fagatele Bay National Marine Sanctuary, the Territorial Marine Park on Ofu and the American Samoa National Park, Ofu segment.

## Open Ocean Waters

Designated uses of open ocean waters include fishing, scientific investigations, boating, support of marine life, and recreation. While there is a small offshore fishery, it is unknown whether offshore waters are affected by pollution. High strength wastes (high solids, high nitrogen, high phosphorus) from the tuna canneries are no longer dumped in a designated zone approximately five miles offshore. Starkist instead utilizes a new improved treatment process to turn the high strength waste into marketable by-products (e.g., fish meal). The process leaves a small amount of residual wastewater that is discharged into the local sewer system.

## II Background

### i. Total Waters

Table 1. Atlas Description of American Samoa

Topic	Value
Territorial Population	55,519*
Territory Surface Area (square miles)	76.1
Total Miles of Streams (miles)	258
Square Miles of Coral Reef	184
Miles of Ocean Coast	149
Acres of Fresh Water and Tidal Wetlands	396

\*From 2010 Census

### ii. Maps

The Territory of American Samoa is divided into 41 watershed units to simplify management of aquatic and terrestrial resources. Maps with watershed delineations are presented in Appendix D, Figures 1 and 2.

### iii. Water Pollution Control Program

#### A. Watershed Approach

The total surface area of American Samoa is very small, only 76.1 sq. miles. This small surface area is divided into 41 watersheds, each with an average size of 1.8 sq. miles (Appendix B, Table 1, Figures 1 and 2). Water quality monitoring, along with coral / fish / benthic monitoring covers 31 out of the 41 watersheds, and also covers >95% of the population of American Samoa. Accordingly, tracking water quality on a watershed scale is fully adequate to meet our monitoring objectives and goals.

#### B. Point Source Program

There are seven identified point sources in the Territory: Starkist Samoa, Samoa Tuna Processors, Utulei Waste Water Treatment Facility (ASPA), Tafuna Waste Water Treatment Facility (ASPA), Pacific Energy (bulk fuel storage and transfer), Satala Power Plant (ASPA), and The American Samoa Shipyard Services Authority. Six of the NPDES permittees discharge to Pago Pago Harbor. Recent analysis of NPDES monitoring data showed that several of these facilities do not meet the requirements established by individual NPDES permits. Compliance by NPDES permittees will improve water quality in American Samoa.

#### C. Nonpoint Source Control Program

American Samoa has determined that all impaired designated uses in the Territory are due to nonpoint sources (NPS). Therefore, watersheds identified as impaired are considered areas where

NPS management measures have not yet improved water quality in the coastal zone. Impaired watersheds are targeted for enhanced management measures and water quality monitoring.

Full approval of the American Samoa Coastal Nonpoint Pollution Control Program (ASCNPP) was received July 24, 2003. In FY14 and FY15 program effort was directed towards full implementation of the program plan.

#### **iv. Cost / Benefit Assessment**

Following are the approximate economic and social costs and benefits of actions necessary to achieve the objective of the Clean Water Act.

##### **Costs:**

- Capital investments in municipal facilities in the past 5 years: 14 million dollars
- Capital investments in municipal facilities in the past 10 years: 19 million dollars
- Capital investments in municipal facilities since 1972: 51 million dollars
- Capital investments in industrial facilities in the past 5 years: 0.01 million dollars
- Capital investments in industrial facilities in the past 10 years: 3.5 million dollars
- Capital investments in industrial facilities since 1972: 10 million dollars
- Investments in nonpoint source measures in the past 5 years: 3.5 million dollars
- Investments in nonpoint source measures in the past 10 years: 5.0 million dollars
- Investments in nonpoint source measures since 1972: 10.0 million dollars
- Annual operation and maintenance costs of municipal facilities: 1.5 million dollars
- Annual operation and maintenance costs of industrial facilities: 4.0 million dollars
- Total annual costs of municipal and industrial facilities: 5.5 million dollars
- Annual costs to government to administer water pollution control activities: 2.0 million dollars.

##### **Benefits:**

Benefits to the territory include the protection of the groundwater that supplies the majority of the drinking water for the Territory, the improved quality of Pago Pago Harbor, which has improved recreational and aesthetic enjoyment as well as habitat and coral reef recovery, protection of beaches and fringing coral reefs from pollution, and increased tourism. The coral reefs around American Samoa are used recreationally and supply much of the fresh fish and seafood for the territory. The reefs also provide a buffer for the islands against the impact of waves.

#### **v. Special Territorial Concerns and Recommendations**

Most special concerns in American Samoa are related to geographical aspects of the islands and cultural aspects of the Samoan people. The main concern is the pressure that the growth in population over the past 30 years in American Samoa is exerting on natural resources and the local environment. There is a very limited land base to accommodate new growth. Only one

third of Tutuila contains land that is suited for human development (i.e., only 19 square miles have a slope of less than 30%). Development factors such as poor land use permitting, overfishing, and increased production of solid waste and sewage will impact groundwater, streams, and coastal waters.

While local environmental education has made great strides in the last decade, there is still a widespread lack of understanding, acknowledgment, and acceptance of environmental issues that affect the Territory. The need to control litter and pig waste is now somewhat understood. However, the effect of pollution from soil erosion, automobiles and untreated sewage is not recognized as a public health and environmental threat. There is a lack of political and public will to enforce most environmental regulations. The regulations themselves are quite comprehensive, but are not seen as a priority for enforcement.

The Malaeimi valley in central Tutuila has been determined to be a major recharge area for the Tafuna-Leone aquifer, which supplies the majority of the drinking water for the Territory. A boil water notice has been in effect in this aquifer area for several years due to bacterial contamination of the aquifer. This valley has been proposed as a Special Management Area, and it is critical that the development in the area is carefully controlled to protect groundwater resources. Unfortunately, the Government has not yet adopted the proposal.

Lastly, the unique coral reef habitat that characterizes the fringing reefs of American Samoa merits special concern. Modern development, leading to road construction, increased solid waste and sewage, and sedimentation, has caused much indirect stress to the coral reefs, while overfishing has directly impacted the reef environment. The concern worldwide for the health and protection of coral reefs is mirrored here in American Samoa. This has led to directed management and research efforts on how to best protect reef habitats.

### III Surface Water Assessment

#### i. Current Surface Water Monitoring Program

##### A. Monitoring Program Description

American Samoa has identified the following monitoring objectives to insure our monitoring program is efficient and effective in generating data that serve all management needs:

- Update water quality standards for all types of Territorial waters
- Determine water quality status and trends for all types of Territorial waters
- Make designated use support determinations and identify impaired waters for all types of Territorial waters
- Identify causes and sources of water quality problems for all types of Territorial waters
- Evaluate the effectiveness of Non Point Source Best Management Practices for restoring impaired designated uses for all types of Territorial waters
- Evaluate the effectiveness of NPDES permits

AS-EPA has developed a Territorial Monitoring and Assessment Program that includes all elements recommended by USEPA. The program incorporates an efficient combination of monitoring plans and strategies to meet all monitoring objectives. The plans/strategies include fixed station, intensive and screening level monitoring, judgmental, and probability designs. Monitoring plans and strategies include:

- AS-EPA Nearshore Marine Water Quality (BEACH) Monitoring Plan
- AS-EPA Stream Water Quality Monitoring Plan
- AS-EPA Probabilistic Monitoring (National Coastal Assessment)
- AS-EPA Coral Reef Monitoring Plan
- Water Quality Monitoring Strategy for Pago Pago Harbor, American Samoa
- American Samoa Coastal Nonpoint Source Monitoring Strategy
- ASPA Drinking Water /Groundwater Systems Water Quality Monitoring Plan
- National Park of American Samoa Water Quality Monitoring Plan

##### B. Monitoring Schedule

Waters that will be monitored and assessed during the next 2-year integrated report cycle include:

- Streams: New stream systems will be assessed according to the plan outlined in the AS-EPA Stream Water Quality Monitoring Plan.
- Ocean Shoreline: Swimming resources will continue to be monitored according to the AS-EPA Nearshore Marine Water Quality Monitoring Plan. Coral reefs will be monitored according to the AS-EPA Coral Reef Monitoring Plan (to assess the effects of NPS pollution on AS Coral Reef Communities).
- Wetlands: No new wetland assessments will be conducted in the period leading up the next integrated report.

- Groundwater: Groundwater will continue to be monitored according to the ASPA Drinking Water /Groundwater Systems Water Quality Monitoring Plan.

## **ii. Status of Plan to Achieve Comprehensive Assessments**

The expanded AS-EPA Territorial Water Quality Monitoring and Assessment Program was designed to be statistically rigorous and to satisfy USEPA guidelines for water quality monitoring programs. All categories of water bodies directly monitored by agency efforts were depicted and inventoried in the program. Sampling locations were geo-referenced with GPS as a collaborative effort with the American Samoa Coastal Management Program (ASCMP).

The Recreational Beach Monitoring Program and the Stream Monitoring Program were created to develop and implement comprehensive monitoring in these aquatic habitats. Fifty recreational beach locations in American Samoa are monitored, 44 weekly, and 6 monthly. This monitoring effort provides excellent coverage for local beach recreational areas. The stream monitoring program is based on a probabilistic model, where a small population of streams are selected at random from the overall population and monitored for 1 year. After that period, a new population of streams is selected at random for monitoring.

The first 4 years of stream monitoring data were analyzed in FY09, and provided a robust assessment of stream water quality in American Samoa. Stream monitoring in FY14 and FY15 was limited to microbiological and physical monitoring. AS-EPA intends to re-implement stream chemical monitoring by FY16.

Other programs, including the AS-EPA Probabilistic Monitoring (NCA) and the AS-EPA Coral Reef Monitoring Program, monitor ocean water quality and coral reef health, and will allow the Territory to achieve comprehensive assessments with the limited resources available.

## **iii. Assessment Methodology**

### **A. Assessment Methodology Description**

#### **1. The 2016 Integrated Report**

AS-EPA assembled and evaluated all existing and readily available data and information from sampling and analyses completed in FY14 and FY15, as well as cumulative assessments from FY03 to FY15, relating to the categories of waters specified in 40 CFR§130.7(b)(5).

Sources for data and information evaluated for this report include:

- AS-EPA Stream Monitoring Program
- AS-EPA Beach Monitoring Program
- ASPA/AS-EPA Groundwater Monitoring Program

For this report, multiple uses based on current water quality standards have been assessed. The primary uses for water bodies in the territory are:

- Potable water supplies (groundwater)

- Support and propagation of indigenous aquatic and terrestrial life (ALUS)
- Compatible recreation and aesthetic enjoyment
- Fish and Shellfish consumption

Use support classifications for this report were changed from those used in previous reports. Fully Supporting, Partially Supporting, and Not Supporting were changed to Fully Supporting (good), Not Supporting (fair), and Not Supporting (poor).

In 2015 census data from the 2010 census was used to update the Watershed Classification for American Samoa. The updated classifications are utilized in this 2016 report.

Specific criteria for determining attainment of these individual uses have been incorporated in accordance with *Guidelines for Preparation of the Comprehensive State Water Quality Assessments (305(b) Reports) and Electronic Updates (USEPA 1997)* and *Guidance for 2006 Assessment, Listing and Reporting Requirements Pursuant to Sections 303(d), 305(b) and 314 of the Clean Water Act* (USEPA 2005) and 2006 Integrated Report Guidance (IRG), supplemented by EPA's 2008, 2010, 2012, 2014, and 2016 memorandums and are described below in detail.

## 2. Assessment Information

The primary unit of assessment used by AS-EPA for this report is the watershed. As indicated previously, the total surface area of American Samoa is very small, only 76.1 sq. miles. This small surface area is divided into 41 watersheds, each with an average size of 1.8 sq. miles (Appendix D, Table 1, Figures 1 and 2). Water quality monitoring, along with coral / fish / benthic monitoring, covers 31 of the 41 watersheds and also covers >95% of the population of American Samoa. Accordingly, tracking water quality on a watershed scale is fully adequate to meet our monitoring and assessment objectives and goals.

Because the watershed is the primary assessment unit, AS-EPA recognizes that data from several locations within a watershed must be reconciled before assessing the overall use support of waters within that watershed. In this regard, when multiple sources of data within one watershed indicated different levels of use support, AS-EPA chose a conservative approach by selecting the least supporting level for the entire watershed.

Two types of assessment information were utilized: "Evaluated" and "Monitored". "Evaluated waters" are those for which the use support decision is based on information other than site-specific ambient data. This includes data on land use, location of sources, and best professional judgment of qualified biologists. "Monitored waters" are those for which the use support decision is principally based on current, site-specific, ambient monitoring data believed to accurately portray water quality conditions. All assessments in this report utilize monitored data.

Each source of Aquatic Life Use Support (ALUS) data, whether "evaluated" or "monitored" is assigned a Data Quality Level in accordance with *Guidelines for Preparation of the Comprehensive State Water Quality Assessments (305(b) Reports) and Electronic Updates (USEPA 1997)*. Data types are grouped into four categories: biological, habitat, toxicological, and physical/chemical. The rigor of a method within each data type is dictated by its technical

components, spatial/temporal coverage, and data quality (precision and sensitivity). Level 4 data are of the highest quality for a data type and provide relatively high level of certainty. Level 1 data represent less rigorous approaches and thus provide a level of information with a greater degree of uncertainty.

### 3. Guidelines for Determining Levels of Use Support for Primary Uses.

#### 3.1 Potable Water Supplies

The 2005 American Samoa Water Quality Standards added definitions for Class 1 and 2 streams. Class 1 has drinking water as a designated use. Class 2 does not have drinking water as a designated use. The assessment framework used for use support decisions for Class 1 waters is shown in Table 3 below.

Table 3. Assessment Framework for Determining Drinking Water Use Support

Classification	Monitoring Data		Use Support Restrictions
Fully Supporting (good)	Contaminants do not exceed water quality criteria	and/or	Drinking water use restrictions are not in effect.
Not Supporting (fair)	Contaminants exceed water quality criteria intermittently	and/or	Drinking water use restrictions resulted in the need for more than conventional treatment with associated increases in cost.
Not Supporting (poor)	Contaminants exceed water quality criteria constantly	and/or	Drinking water use restrictions resulted in closures.
Unassessed	Source water quality has not been assessed for contaminants used or potentially present.		

#### 3.2 Support and Propagation of Indigenous Aquatic and Terrestrial Life

Of the four data type categories (biological, habitat, toxicological and physical/chemical), only new data in one category, physical/chemical, was available during this reporting period for Aquatic Life Use Support (ALUS) determination. These data are of varying data quality levels as per the hierarchy of data levels for evaluation of aquatic life use attainment of the 1997 305(b) EPA guidance. The guideline for determining ALUS using more than one type of data is shown in Table 4 below.

Table 4. Determination of ALUS Using More Than One Data Type

<b>ALUS Attainment</b>	
Fully Supporting	No impairment indicated by all data types.
<b>ALUS Non-Attainment</b>	
*Not Supporting (fair)	Impairment indicated by one or more data types and no impairment indicated by others.
*Not Supporting (poor)	Impairment indicated by all data types.
*A determination of <i>Not Supporting (fair)</i> or <i>Not Supporting (poor)</i> could be made based on the nature and rigor of the data and site-specific conditions in the results of the data types. If bioassessment (usually Level 3 or 4) indicates impairment, then a determination of <i>Not Supporting (poor)</i> should be made.	

**i. Physical/Chemical Methods**

USEPA guidance (1997) states the importance of incorporating the established criteria for conventionals and toxicants in ALUS determinations and to use the “worst case” approach where multiple parameters are available (USEPA, 1997). Tables 5 and 6 below, describe the decision guidelines used for determining ALUS using Physical/Chemical Methods for conventional data (and additional parameters) and toxicant data.

Conventional pollutants are defined by the Clean Water Act of 1977 as BOD, TSS, fecal coliform, oil and grease, and pH. Additional parameters analyzed by AS-EPA include Temperature, Dissolved Oxygen, Turbidity, Total Nitrogen, Total Phosphorus, and Enterococcus. These parameters were assessed by the criteria developed by the USEPA for the “Conventional Category”. Priority pollutants include all pollutants listed as Priority Pollutants by the Clean Water Act and subsequent amendments to the act. No priority pollutant monitoring was conducted in FY14 or FY15.

Much of AS-EPA’s Physical/Chemical data is considered Low/Moderate quality, based on technical components and spatial/temporal coverage, as defined by Table 3-4 in the 1997 EPA guidance document Hierarchy of Physical/chemical Data Levels for Evaluation of Aquatic Life Use Attainment. The ASWQS provides standards for these parameters presented in Table C1 (Appendix C).

Table 5. Decision Guidelines for Conventionals (and additional parameters) Used to Assess ALUS in Freshwater Rivers and in Marine Waters

Degree of Aquatic Life Use Support	Criteria for Conventionals*
Fully Supporting (good)	For any one pollutant, ASWQS exceeded in $\leq 10$ percent of measurements.
Not Supporting (fair)	For any one pollutant, ASWQS exceeded in 11 to 25 percent of measurements.
Not Supporting (poor)	For any one pollutant, ASWQS exceeded in $>25$ percent of measurements.

\* Conventional statistical parameters (Turbidity, Total Phosphorus, Total Nitrogen, Chlorophyll a, Light Penetration, and Total Suspended Solids) are compared to the “Median not to exceed” WQS value.

Table 6. Decision Guidelines for Toxicants (priority pollutants, metals, chlorine and ammonia) Used to Assess ALUS in Freshwater Rivers and in Marine Waters

Degree of Aquatic Life Use Support	Criteria for Toxicants*
Fully Supporting (good)	For any one pollutant, no more than 1 exceedance of acute criteria within a 3-year period based on grab or composite samples and no more than 1 exceedance of chronic criteria within a 3-year period based on grab or composite samples
Not Supporting (fair)	For any one pollutant, acute or chronic criteria exceeded more than once within a 3-year period, but in $\leq 10$ percent of samples.
Not Supporting (poor)	For any one pollutant, acute or chronic criteria exceeded in $>10$ percent of samples.

\* ASWQS state that for toxic substances, compliance shall be determined by any single sample, unless otherwise specified by the Environmental Quality Commission.

## ii. Habitat Assessment and Bioassessment

In FY14 and FY15, the AS-EPA stream monitoring program did not include a habitat assessment. No stream bioassessment data were collected during this period.

No coral reef bioassessments were collected in FY14 and FY15.

Guidelines from the USEPA guidance (1997) for ALUS determination using habitat assessment data are provided in Table 7 below.

Guidelines from the USEPA guidance (1997) for ALUS determination using bioassessment data are provided in Table 8 below. These guidelines were not developed for coral reef bioassessments. Therefore, a modified assessment methodology was developed by Dr. Peter Houk (UOG Marine lab) and is provided below.

### Study Design

Three reef types have been identified during the course of ASEPA monitoring efforts: 1) primary framework with interstitial spaces common throughout the reef matrix, found mainly on the south side of Tutuila, and 2) primary framework with a well-cemented, underlying basement, lacking significant interstitial spaces, mainly found on the northern side of the island, and 3) intermixed sand and primary-framework reef patches. Primary coral framework (Holocene) were defined by a consolidated reef matrix created mainly by large coral skeletons cemented together with coralline algae, and interstitial spaces refer to the presence of cavities within the primary reef framework. Present monitoring designs are mainly focused on the first two reef types because they are the most predominant, and classified by geography (i.e., reef types 1 and 2 represents reefs along the south and north shore of Tutuila, respectively). Within each of the two major reef types, representative sites are selected for investigation in accordance with watershed sizes, several proxies of watershed pollution, and along a gradient of wave exposure.

### Ecological Data

Monitoring sites are established on the nearshore reef slopes (8–10 m) adjacent to selected watersheds, approximately 250 m away from stream discharge. During each survey event, a hand held global positioning system unit is used to identify the location of transects that are placed at a uniform depth of 9 – 11 m, with a known geographic heading. Benthic cover is evaluated using video and photo quadrat protocols along a series of transect lines. Transect lines are separated into 6 x 25 m long replicates, and benthic substrate abundances are estimated from photographs of 0.5 x 0.5 m quadrats taken at 1 m intervals. Photographs are analyzed by projecting five random dots on the screen and noting the life form under each of the dots. The benthic categories chosen for analysis are corals (to genus level), turf algae (less than 2 cm), macroalgae (greater than 2 cm, to genus level if abundant), fleshy coralline algae known to overgrow coral (*Peyssonnelia*, *Pneophyllum*), calcifying crustose coralline algae, sand, and other invertebrates (genus level if abundant). From these categories, a benthic substrate ratio is classified as the percent cover of calcifying corals and crustose coralline algae divided by the percent cover of turf, macroalgae, and fleshy coralline algae substrate. High benthic substrate ratios indicate favorable reef condition, and dominance of calcifying substrates that accrete through time.

At each location coral communities are examined using a point quadrat technique. Ten replicate 1 x 1 m quadrats are haphazardly tossed at equal distances along the transect lines. Every colony whose center point lay inside the quadrat is recorded to species level, and the maximum diameter and diameter perpendicular to the maximum is measured. These measurements are used to estimate percent coverage, relative abundance, population density,

and geometric diameter, with the mathematical assumption that colonies are circular. Margalef's d-statistic is calculated as a measure of the number of corals present, making some allowance for the abundance of individuals, or community evenness. This describes how evenly coral coverage was distributed at each site, but does not take overall percent cover into account. A low d-statistic suggests that coral coverage was not dominated by one, or a few, species.

Fish numerical abundance and biomass are estimated using a modified stationary point count (SPC) protocol. An observer takes measurements within 12 replicate SPCs using a 7.5 m radius for a period of 3-minutes. Food fish are defined by acanthurids, scarids, serranids, carangids, labrids, lethrinids, lutjanids, balistids, kyphosids, mullids, and holocentrids that are known to be harvested. Fish biomass estimates are calculated using the length assessments recorded during the SPCs. The biomass is calculated by using the formula  $W=A*L^B$  where  $W$ =weight,  $L$ = length, and  $A$ & $B$ = growth parameters obtained from [www.fishbase.org](http://www.fishbase.org). When growth parameters were not known for a given species, values from a closely related species are used.

In order to account for varying SPC observation times, fish abundances are estimated for individual SPCs by dividing the biomass by the amount of time spent observing the fish.

Macroinvertebrates have been counted along the transect lines used for benthic assessments since the inception of ASEPA monitoring efforts. However, it was found that macroinvertebrate populations are extremely scarce at all monitoring locations, and consistently have standard deviations that are over double the mean values. Therefore, macroinvertebrate data are no longer assessed.

### Environmental Data

Wave exposure data is gathered from NOAA Wave Watch III model predictions, summarized for American Samoa. For each monitoring site, mean wave heights are recorded with respect to their angle of exposure, using the wave-rose data, and the sum of wave intensity for all angles of exposure was calculated for each site.

Watersheds adjacent to each site are quantified using existing American Samoa Department of Commerce GIS layers pertaining to land use and boundaries. Disturbed land included all regions that no longer have tropical rainforest as the dominant tree cover, based upon United States Forest Service vegetation maps (<http://www.fs.usda.gov/r5>). Human population estimates are derived from the most recent census report.

### Data Analysis

#### *Reef Types and Geography –*

Examinations are first conducted to describe the inherent differences between coral, fish, and benthic assemblages along the south shore of Tutuila compared with the north (i.e., framework reefs with interstitial spaces in the south versus predominately consolidated reef in

the north). For all assemblages, data is aggregated at the site level, and species-by-site matrices are generated and used to create Bray-Curtis similarity matrices. Bray-Curtis similarity matrices are calculated by:

$$S_{(j, k)} = 1 - (\sum |Y_{ij} - Y_{ik}| / \sum (Y_{ij} + Y_{ik}))$$

where S represents the ecological similarity between two sites (j and k),  $\sum$  (numerator) represents the summation of the absolute differences in the abundance of each species ( $Y_i$ ) at the two sites, and  $\sum$  (denominator) represents the sum of the abundances of species ( $Y_i$ ) at the two sites. Bray-Curtis similarities define how consistent species abundance patterns were between each pair of sites. Similarity matrices are graphically interpreted using principle components ordination plots that depict the site-based distances into two-dimensional space. Significance between reef types is calculated from PERMANOVA tests that are similar to standard ANOVA tests that calculate significance based upon Bray-Curtis variation within and across reef types. These tests provide a pseudo-F statistic that is analogous to a standard ANOVA test result, and a P-value based upon permutation, or repeating the process until a probability distribution is generated.

Table 7. ALUS Determination Based on Habitat Assessment Data

Degree of Aquatic Life Use Support	Criteria
Fully Supporting (good)	Reliable data indicate natural channel morphology, substrate composition, bank/riparian structure, and flow regime of region. Riparian vegetation of natural types and of relatively full standing crop biomass (i.e., minimal grazing or destructive pressure).
Not Supporting (fair)	Modification of habitat slight to moderate usually due to road crossings, limited riparian zones because of encroaching land-use patterns, and some watershed erosion. Channel modification slight to moderate.
Not Supporting (poor)	Moderate to severe habitat alteration by channelization and dredging activities, removal of riparian vegetation, bank failure, heavy watershed erosion or alteration of flow regime.

Table 8. ALUS Determination Based on Bioassessment Data

Degree of Aquatic Life Use Support	Criteria
Fully Supporting (good)	Reliable data indicate functioning, sustainable biological assemblages (e.g. fish, macroinvertebrates, or algae) none of which has been modified significantly beyond the natural range of the reference condition.
Not Supporting (fair)	At least one assemblage (e.g. fish, macroinvertebrates, or algae) indicates moderate modification of the biological community compared to the reference condition.
Not Supporting (poor)	At least one assemblage indicates nonsupport. Data clearly indicate severe modification of the biological community compared to the reference condition.

Data levels for the four data type categories were ranked according to the hierarchy provided in the USEPA guidance (1997).

### 3.3 Recreation and Aesthetic Enjoyment

The current ASWQS lists Enterococci and *E.coli* as the microbiological indicators for fresh surface waters and Enterococci as the indicator for microbiological quality in marine waters.

Microbiological criteria used to determine use support for waters designated for whole body contact recreation are depicted in Table 9 below. The assessment methodology for determining whole body recreational contact in the 2008 report was based on the percentage of single sample exceedances. In the 2010 report, single sample maximum exceedances and the percentage of 5 week rolling geomean exceedances were included in the assessment methodology. Since the 2012 report, in addition to the single sample maximum exceedances, the annual geomean exceedances were used instead of percentage of 5 week rolling geomean exceedances.

In 2013 American Samoa adopted revised WQS which included the USEPA 2012 Recreational Water Quality Criteria. The revised ASWQS were approved by USEPA Region 9 in 2014.

In 2014 AS-EPA identified 130 MPN enterococci/100 ml as the appropriate BAV for American Samoa's tropical marine waters. AS-EPA implemented use of the BAV on 01 October 2014. A formal justification for the BAV was approved by USEPA Region 9 in January 2015.

Table 9. Whole Body Contact Recreation (all surface and marine water designations)

Level of Recreation Use Support	Criteria	
	Fresh Surface Water	Marine Water (Embayments, Open Coastal, Ocean)
Fully Supporting (good)	<p><u>E. coli</u>: The statistical threshold value of 410 per 100 mL is exceeded in ≤10 percent of measurements AND the annual geometric mean does not exceed 126.</p> <p><u>Enterococci</u>: The statistical threshold value of 130 per 100 mL is exceeded in ≤10 percent of measurements AND the annual geometric mean does not exceed 35.</p>	<p><u>Enterococci</u>: The statistical threshold value of 130 per 100 mL is exceeded in ≤10 percent of measurements AND the annual geometric mean does not exceed 35.</p>
Not Supporting (fair)	<p><u>E. coli</u>: The statistical threshold value of 410 per 100 mL is exceeded in 11 to 25 percent of measurements OR the annual geometric mean of 126 is exceeded.</p> <p><u>Enterococci</u>: The statistical threshold value of 130 per 100 mL is exceeded in 11 to 25 percent of measurements OR the annual geometric mean of 35 is exceeded.</p>	<p><u>Enterococci</u>: The single statistical threshold value of 130 per 100 mL is exceeded in 11 to 25 percent of measurements OR the annual geometric mean of 35 is exceeded.</p>
Not Supporting (poor)	<p><u>E. coli</u>: statistical threshold value of 410 per 100 mL is exceeded in &gt;25 percent of measurements OR the annual geometric mean of 126 is exceeded.</p> <p><u>Enterococci</u>: statistical threshold value of 130 per 100 mL is exceeded in &gt;25 percent of measurements OR the annual geometric mean of 35 is exceeded.</p>	<p><u>Enterococci</u>: The statistical threshold value of 130 per 100 mL is exceeded in &gt;25 percent of measurements OR the annual geometric mean of 35 is exceeded.</p>

### 3.4 Fish and Shellfish Consumption

Based on the results of the 2005 AS-EPA Tier II Fish Toxicity study, the fish consumption advisory continues to exist for fish and shellfish in the inner Pago Pago Harbor. The USEPA guidance document (1997) provided classification hierarchy for use support status based on fish/shellfish consumption advisory data as depicted in Table 10 below.

Table 10. Fish/Shellfish Consumption Use Support Determination Based on Advisory Data

Degree of Aquatic Life Use Support	Criteria*
Fully Supporting (good)	No fish/shellfish restrictions or bans are in effect.
Not Supporting (fair)	“Restricted consumption” of fish in effect. Restricted consumption is defined as limits on the number of meals or size of meals consumed per unit of time for one or more fish/shellfish species. Or, a fish or shellfish ban in effect for a subpopulation that could be at potentially greater risk, for one or more fish/shellfish species.
Not Supporting (poor)	“No consumption” of fish or shellfish ban in effect for general population for one or more fish/shellfish species, or commercial fishing/shellfishing ban in effect.

\* Fish/Shellfish consumption restrictions shall be determined based on *Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories. Risk Assessment and Fish Consumption Limits. Third Edition* (USEPA 2000). For target species, collect 3-10 individuals for each of 3-5 composites. Ranges are given due to highly variable abundance among coral reef fish species. Size-class composite analysis is not practicable for coral reef fish, since reef fish do not follow typical age-size relationships found for pelagic and temperate fishes (see *Tier 2 fish toxicity study. Chemical contaminants in fish and shellfish and recommended consumption limits for Territory of American Samoa*, 2005, by Peshut and Brooks).

### 4. Guidelines for Determining Consolidated Assessment and Listing Methodology (CALM) Categories

The Consolidated Assessment and Listing Methodology (CALM) categories for this report were determined from the *Guidance for 2006 Assessment, Listing and Reporting Requirements Pursuant to Sections 303(d), 305(b) and 314 of the Clean Water Act* (USEPA 2005). Each water body type was assigned a CALM category, based on the following descriptions.

- Category 1 Water body meets all designated uses. No use is impaired.
- Category 2 Water body meets some of the designated uses. There is insufficient data to evaluate any remaining designated uses.
- Category 3 There are insufficient data to evaluate any designated uses.
- Category 4a Water body is impaired for one or more designated uses, but a TMDL has already been prepared and completed.

- Category 4b Water body is impaired for one or more designated uses, but a TMDL is not necessary because other pollution control requirements are reasonably expected to result in the attainment of the water quality standard in the near future.
- Category 4c Water body is impaired for one or more designated uses, but a TMDL is not necessary because a pollutant does not cause the impairment.
- Category 5 Water body is impaired, and a TMDL is required [303(d) list].

#### ***iv. Streams Water Quality Assessment – FY14 and FY15 Data only***

Using the guidelines presented above, American Samoa’s stream waters were assessed according to levels of use support. This information is presented in Tables C2 through C4 in Appendix C and summarized in Appendix B.

AS-EPA gathered water quality data from streams in the Territory. All data were Monitored Data, no Evaluated Data was used for this report. The assessment of these data covers 104.9 miles out of 257.5 total stream miles (Table B2). The Assessed Goals were 1) Protect and Enhance Public Health (Whole Body Contact Recreation/Swimming) and 2) Protection and Enhancement of Ecosystems (Aquatic Life). All other categories were either “Not Applicable” or “Applicable but no data was available” for this reporting period (Table C2). The Major Cause/Stress identified for this reporting period was Pathogen Indicators (Table C3). The major assessed sources of impairment were Collection System Failure and Intensive Animal Feeding Operations (Table C4). Trend analyses will be developed as stream monitoring continues and data accrues.

For the goal to Protect and Enhance Public Health, 104.9 stream miles were assessed for Swimming and all found to be Not Supporting (poor) (Table C2).

For the goal Protect and Enhance Ecosystems (Aquatic Life) 90.5 miles were assessed. Of this total, 83.0 miles were Fully Supporting (good), 7.5 miles were Not Supporting (fair), and 0.0 miles were Not Supporting (poor) (Table C2).

The following CALM categories were assigned based on the assessments for Swimming and ALUS (Tables B1 and B2). Of the 31 watersheds with streams, 20 watersheds were placed in Category 3 (152.6 miles). Ten watersheds were placed in Category 4a (97.4 miles) because a TMDL was completed and approved. One watershed was placed in Category 5 (7.5 miles)

#### ***v. Ocean Shoreline Assessment – FY14 and FY15 Data only***

Using the guidelines presented above, American Samoa’s ocean shoreline waters were assessed according to levels of use support. All data were Monitored Data, no Evaluated Data was used for this report. This information is presented in Tables C5 through C7 in Appendix C and summarized in Appendix B.

For this reporting period the total size assessed in shoreline miles was 111.2 out of 149.5 total shoreline miles (Table B2). The Assessed Goals were Protection and Enhancement of Public Health (Fish Consumption and Whole Body Contact Recreation/Swimming). All other categories were either “Not Applicable” or “Applicable but no data was available” for this reporting period (Table C5). The Major Causes/Stresses identified for this reporting period were PCBs, Metals (Mercury), and Pathogen Indicators. (Table C6). The Major sources of impairment were Collection System Failure and Intensive Animal Feeding Operations (Table C7). Trend analyses will be developed as the Territorial coral reef and marine monitoring program continues and data accrues.

For the goal to Protect and Enhance Public Health, 103.3 shoreline miles were assessed for swimming. Of this total, 51.3 miles were Fully Supporting, 3.3 miles were Not Supporting (fair), and 48.7 miles were Not Supporting (poor) (Table C5).

For the goal to Protect and Enhance Public Health, 7.9 shoreline miles were assessed for fish consumption, and 7.9 miles were found to be Not Supporting (poor) (Table C5).

The following CALM categories were assigned based on the assessments for Aquatic Life Use Support and Swimming (Tables B1 and B2). Twelve of the 41 watersheds in American Samoa were given a CALM Category 2 (51.3 miles). Thirteen watersheds received a Category 3 rating (46.1 miles). Sixteen watersheds received a Category 4a rating (52.0 miles) because a TMDL was completed and approved.

#### ***vi. Wetlands Assessment – only FY14 and FY15 Data***

No wetlands assessments were conducted during this reporting period. All watersheds that contain wetlands (14 out of 41) were placed in CALM category 3 (396.0 acres). Wetland assessment information is presented in Tables B8 through B10.

#### ***vii. Long Term CWA 303(d) Program Priorities and Schedule for Establishing TMDLs / 303 (d) List***

Clean Water Act (CWA) long term program priorities through FY2022 are consistent with the 2016 Integrated Report priority ranking for TMDL development provided in Appendix A. The program’s highest priority is TMDL development for nutrients (Total Nitrogen and Total Phosphorus) in streams. The rationale for this prioritization is that the streams are recognized as the major source of nutrients to ocean shoreline waters and likely major NPS stressors to the coral reefs.

A TMDL for the pollutant enterococcus in beaches and streams was completed in 2013 and approved by USEPA in 2015.

Because of American Samoa’s small size and the limited number of people involved with CWA activities in American Samoa the CWA 303(d) program priorities are closely integrated with the

American Samoa Water Quality Standards, all water quality monitoring efforts, NPDES, source water protection, and conservation programs.

American Samoa utilizes the Integrated Report public notice process as a means to engage the public on establishing CWA 303(d) priorities.

### ***viii. Evaluating Pollutants/Surface Waters for Removal from the 303(d) List***

AS-EPA shall remove a pollutant of a surface water from the 303(d) list based on one or more of the following criteria:

- USEPA approved a TMDL for the pollutant;
- The data used for previous listing is superseded by more recent credible and scientifically defensible data showing that the surface water meets the applicable numeric or narrative surface water quality standard. All historical data is considered, with a greater weight placed on more recent (last 3 – 5 years) data, except for Ocean Shoreline (beaches for swimming), with a greater weight placed on the last 2 years because of the large number of samples collected;
- The surface water no longer meets the criteria for impairment based on a change in the applicable water quality standard or a designated use approved by USEPA;
- The surface water no longer meets the criteria for impairment for the specific narrative water quality standard based on a change in narrative water quality standard implementation procedures;
- A re-evaluation of the data indicate that the surface water does not meet the criteria for impairment because of a deficiency in the original analysis; or
- Pollutant loadings from naturally occurring conditions alone are sufficient to cause a violation of applicable water quality standards.

AS-EPA shall remove a surface water from the 303(d) list if all pollutants for the surface water or segment are removed from the list.

### ***ix. Pollutant/Surface Water Combinations Removed from the 303(d) List***

No waterbodies were removed from the 303(d) list in this reporting period.

AS-EPA considered removing the pollutant enterococcus for the ocean shoreline in Watersheds 14 (Sailele), 32 (Nua-Seetaga), and 33 (Amanave) because the assessments for these watersheds changed from Not Supporting (fair) in 2014 to Fully Supporting in 2016. However, AS-EPA decided to wait until 2018 assessments are completed to ensure the removal is scientifically defensible.

### ***x. Results of Probabilistic-based Surveys***

In 2015, USEPA partnered with American Samoa EPA, CNMI DEQ, and Guam EPA to implement a Reef Flat survey effort in these Territories as part of the 2015 National Coastal Assessment (NCA). Fifty sampling locations on reef flats in each Territory were established within a probabilistic sampling framework. Indicator parameters were measured at all selected sampling sites. Indicators included water column hydrography (temperature, pH, dissolved oxygen, salinity, PAR), water chemistry (chlorophyll *a*, total nitrogen, dissolved inorganic nitrogen, total phosphorus, dissolved inorganic phosphorus, silicates), microbiology (enterococci), and a bioassessment (characterization of the major floral and faunal composition). Sampling for American Samoa was conducted in July 2015.

Principal survey objectives included:

1. Conduct a comprehensive survey of water quality indicators on the reef flats of Tutuila and Aunuu islands, utilizing the probabilistic design approach developed by NCA. A reef flat is defined as the shallow area between the shoreline intertidal zone and the reef crest of a fringing reef. The reef crest is defined as the sharp break in slope at seaward margin or edge of reef flat. The reef crest is typically slightly elevated compared to the reef flat and is the location of primary breakers.
2. Compare collected data with numerical criteria to develop a “snapshot” of current water quality conditions.
3. Compare results to the baseline established in 2010 to evaluate how the conditions of the reef flat resources of American Samoa change over time. Repeated reef flat surveys on the order of every 5 years can then detect trends in environmental conditions.

Reef flat conditions will be assessed by two water quality criteria, ASWQS (compliance or non compliance with numerical standards) and NCA draft criteria for Tropical Waters. Conditions will also be assessed by benthic integrity rankings. Results will be available for the 2018 Integrated Water Quality Report

### ***xi. Cumulative Use Support Summary***

The narrative section of the 2016 report, as well as assessments presented in Appendix B and Appendix C, reflect data collected in FY14 and FY15 only.

A cumulative assessment that reflects all data collected between FY03 and FY15 is presented in Appendix A. For this summary, the lowest level of use support was used for watersheds where use support determination differed from year to year, except where a pollutant or watershed has been removed from the Section 303(d) list. Since wetland data was low precision evaluated data, all wetlands were assigned to CALM Category 3.

## IV Groundwater Assessment

Tables 12 to 14 report on the quality of the Tutuila, Ofu/Olosega and Ta'u aquifers that provide the majority of American Samoa's ground water resources. Table 12 provides an overview of the most important sources of ground water contamination. Best professional judgment provided the methodology and justification for prioritization of the sources indicated. In the same table, letters in the third column correspond with the following concerns for each contaminant source.

- A. Human health and/or environmental risk (toxicity)
- B. Size of population at risk
- C. Location of sources relative to drinking water sources
- D. Number and/or size of contaminant sources
- E. Hydrogeologic sensitivity
- F. Territorial findings, other findings
- H. Geographic distribution/occurrence

As well, letters in the fourth column correspond with the contaminants/classes of contaminants considered to be associated with each of the sources that were checked.

- A. Inorganic pesticides
- B. Organic pesticides
- C. Halogenated solvents
- D. Petroleum compounds
- E. Nitrate
- G. Salinity/brine
- H. Metals
- I. Radionuclides
- J. Bacteria
- K. Protozoa
- L. Viruses

Table 13 provides a summary of American Samoa's ground water protection efforts. AS-EPA and other cooperating government agencies have increased efforts to monitor and protect groundwater resources. Table 14 provides and ground water contaminant summary for the Tutuila aquifer. Tables 15-22 provide the occurrence of particular groups of contaminants for each hydrogeologic setting in American Samoa. In FY12 continuous boil water notices due to E.coli were published for the Tafuna Plains area of the ASG Central public water system. Currently, a Ground Water Under the Direct Influence of Surface Water (GUDI) study has been completed on 40 wells, and no new GUDI wells have been detected in the system other than the 9 wells that have already been determined GUDI. This is the cause of the current Boil Water Notice in areas of the ASPA water system. ASPA already shutdown 1 of the 9 GUDI Wells and is working diligently to drill replacement wells so the Boil Water Notice can be lifted.

Table 12: Major Sources of Ground Water Contamination

Contaminant Source	Ten Highest Priority Sources	Factors Considered in Selecting a Contaminant Source	Contaminants

## **V Public Participation Process**

As part of the integrated report process, AS-EPA announced the completion of the Integrated Water Quality Monitoring and Assessment Report and solicited public comments over a 30-day period. The public announcements were advertised in a local newspaper and on the ASEPA website, and the document was made available to any interested member of the public to review and provide comments. ? comments were received.

<b>CALM Assessment Category</b>										3		3			3		3	3				3					3			3					3	3	3		3			3		3					

Note: In watersheds where samples were taken at more than one site, the lowest level of use support was used for the summary.

Legend

Shaded areas indicate watersheds that do not have the waterbody type for evaluating designated use, or, the designated use does not apply for the waterbody in that watershed.

Designated Use Support Level
F - Fully Supporting (good)
N <sup>f</sup> - Not Supporting (fair)
N <sup>P</sup> - Not Supporting (poor)

Development Category
pr - pristine
in - intermediate
ex - extensive

CALM Assessment Category
1 - All Designated Uses (DUs) met
2 - Some DUs met; insufficient data to evaluate remaining DUs
3 - Insufficient data to evaluate any DUs
4a - Water is impaired; TMDL not needed
5 - Water is impaired; TMDL needed

Note: All Waterbodies (Streams) have only ASWQS Class 2 designated uses

Note: In watersheds where use support determination differed from year to year the lowest level of use support was used for this summary, except where a pollutant or watershed has been removed from the 303(d) list.

**Table A2. Size of Surface Waters Assigned to Reporting Categories Summary (Cumulative: Includes all FY03 to FY015 data)**

Waterbody Type	Category							Total in Territory	Total Assessed
	1	2	3	4a	4b	4c	5		
<b>Stream, Miles</b>	0.0	13.0	26.9	43.9	0.0	0.0	173.7	257.5 miles	230.6
<b>Ocean Shoreline, Miles</b>	5.2	41.1	25.0	29.6	0.0	0.0	48.6	149.5 miles	124.5
<b>Wetlands, Acres</b>	0.0	0.0	396.0	0.0	0.0	0.0	0.0	396.0	0.0

**CALM Assessment Category**

- 1-- All Designated Uses (DUs) met.
- 2-- Some DUs met; insufficient data to evaluate remaining Dus.
- 3-- Insufficient data to evaluate any DUs.
- 4-- Water is impaired; TMDL not needed.
- 4a- Impaired or threatened for one or more designated uses but does not require the development of a TMDL because TMDL had been completed.
- 4b- Impaired or threatened for one or more designated uses but does not require the development of a TMDL because other pollution control requirements are reasonably expected to result in the attainment of the water quality standard in the
- 4c- Impaired or threatened for one or more designated uses but does not require the development of a TMDL because impairment is not caused by a pollutant.
- 5-- Water is impaired; TMDL needed.

<b>CALM Assessment Category</b>										3	3				3		3	3			3			3			3			3																							

Note: In watersheds where samples were taken at more than one site, the lowest level of use support was used for the summary.

Legend

Shaded areas indicate watersheds that do not have the waterbody type for evaluating designated use, or, the designated use does not apply for the waterbody in that watershed.

Designated Use Support Level
F - Fully Supporting (good)
N <sup>f</sup> - Not Supporting (fair)
N <sup>P</sup> - Not Supporting (poor)

Development Category
pr - pristine
in - intermediate
ex - extensive

CALM Assessment Category
1 - All Designated Uses (DUs) met
2 - Some DUs met; insufficient data to evaluate remaining DUs
3 - Insufficient data to evaluate any DUs
4a - Water is impaired; TMDL completed
5 - Water is impaired; TMDL needed

Note: Watershed 24 (Pago Pago) placed in Category 4a for Fish Consumption (TMDL completed in 2007) but remains in Category 5 for Swimming

Note: All Waterbodies (Streams) have only ASWQS Class 2 designated uses

**Table B2. Size of Surface Waters Assigned to Reporting Categories for 2016 (FY14 and FY15 data only)**

Waterbody Type	Category							Total in Territory	Total Assessed
	1	2	3	4a	4b	4c	5		
Stream, Miles	0.0	0.0	152.6	97.4	0.0	0.0	7.5	257.5 miles	104.9
Ocean Shoreline, Miles	0.0	51.3	46.1	52.0	0.0	0.0	0.0	149.5 miles	103.3
Wetlands, Acres	0.0	0.0	396.0	0.0	0.0	0.0	0.0	396.0	0.0

**CALM Assessment Category**

- 1-- All Designated Uses (DUs) met.
- 2-- Some DUs met; insufficient data to evaluate remaining Dus.
- 3-- Insufficient data to evaluate any DUs.
- 4-- Water is impaired; TMDL not needed.
- 4a- Impaired or threatened for one or more designated uses but does not require the development of a TMDL because TMDL had been completed.
- 4b- Impaired or threatened for one or more designated uses but does not require the development of a TMDL because other pollution control requirements are reasonably expected to result in the attainment of the water quality standard in the near future.
- 4c- Impaired or threatened for one or more designated uses but does not require the development of a TMDL because impairment is not caused by a pollutant.
- 5-- Water is impaired; TMDL needed.

## VIII Appendix C

Table C1: Summary of American Samoa Water Quality Standards

Parameters	Fresh Surface Waters	Embayments	Pago Harbor Embayment	Embayments (Fagatele Bay and Pala Lagoon)	Open Coastal Waters	Ocean Waters
Temperature	-not to deviate more than 1.5 °F from ambient and not to fluctuate more than 1 °F on an hourly basis or to exceed 85 °F (except when due to natural causes)					
Light Penetration Depth	not < 65.0 ft (to exceed given value 50% of the time)	not < 120.0 ft (to exceed given value 50% of the time)	not < 65.0 ft (to exceed given value 50% of the time)	not < 130.0 ft (to exceed given value 50% of the time)	not < 130.0 ft (to exceed given value 50% of the time)	not < 150.0 ft (to exceed given value 50% of the time)
PH	6.5-8.6 range (+/- 0.2 pH units of that which would naturally occur)	6.5-8.6 range (+/- 0.2 pH units of that which would naturally occur)	6.5-8.6 range (+/- 0.2 pH units of that which would naturally occur)	6.5-8.6 range (+/- 0.2 pH units of that which would naturally occur)	6.5-8.6 range (+/- 0.2 pH units of that which would naturally occur)	6.5-8.6 range (+/- 0.2 pH units of that which would naturally occur)
Dissolved Oxygen	not < 75% saturation or not <6.0 mg/L	not < 70% saturation or not <5.0 mg/L	not < 70% saturation or not <5.0 mg/L	not < 80% saturation or not <5.5 mg/L	not < 80% saturation or not <5.5 mg/L	not < 80% saturation or not <5.5 mg/L
Turbidity <sup>1</sup>	not > 5.0 NTU	not > 0.35 NTU	not > 0.75 NTU	Fagatele Bay not >0.25 NTU; Pala Lagoon not >0.75 NTU	not > 0.25 NTU	Not > 0.20 NTU
